## Personal Wealth, 2004

by Brian G. Raub

In 2004, there were an estimated 2.7 million adults with gross assets of $\$ 1.5$ million or more, the Federal estate tax filing threshold for decedents from that year. In total, these top wealth holders owned nearly $\$ 11.1$ trillion in assets. After accounting for debts and mortgages of $\$ 850.1$ billion, these individuals had a combined net worth of over $\$ 10.2$ trillion. Although top wealth holders made up only about 1.2 percent of the total U.S. adult population, they held 20.3 percent of the total U.S. net worth in 2004.1,2

## Background

The distribution and composition of personal wealth in the United States are topics of great interest among researchers and policy planners. Unfortunately, these issues are difficult to research, since there are few sources of data on the wealth holdings of the general population, especially the very rich. Federal estate tax returns (Form 706) provide a unique source from which to study the nation's wealthiest individuals.

The estate tax return contains a complete listing of a decedent's assets and debts, as well as a demographic profile of the decedent and information on the costs of administering the estate. A decedent's estate has up to 9 months to file an estate tax return, but use of a 6 -month extension is common. It is, therefore, necessary to combine returns filed over a number of calendar years in order to capture data representative of all estate tax decedents dying in a single year.

The estate multiplier technique is used to estimate the wealth of living individuals from Federal estate tax return data. The fundamental assumption underlying this methodology is that estate tax returns filed for decedents who died in a particular year represent a random sample, designated by death, of the living population in that year. Estimates of the wealth holdings of the living population are derived

Brian G. Raub is an economist with the Special Studies Special Projects Section. This article was prepared under the direction of Barry Johnson, Special Studies Branch Chief.
by applying a multiplier, based on appropriate mortality rates, to this sample.

## Valuation Measures

The level of wealth to which these estimates apply is $\$ 1.5$ million or more in gross assets, the Federal estate tax filing threshold in effect for 2004 U.S. decedents. Gross assets as defined here are a Federal estate tax concept of wealth that does not conform to usual definitions of wealth. Therefore, three measures of wealth are used in this article: gross assets, total assets, and net worth.

Gross assets reflect the gross value of all assets, including the full face value of life insurance, reduced by the value of any policy loans, but excluding any reduction for other indebtedness or for special valuation of some real estate. This measure defines the individuals included in the top wealth holder group.

Total assets are a lower wealth value, but still essentially a gross measure. They differ from gross assets in that the cash, or equity, value of life insurance (i.e., the value of insurance immediately before the policyholder's death) replaces the "at death" value of life insurance included in gross assets. ${ }^{3}$

Total assets are the valuation concept on which all the analyses in this article are based. Net worth is total assets minus debts.

## Demographic Characteristics

Of the 2.7 million individuals in 2004 who had gross assets of at least $\$ 1.5$ million, almost 1.6 million, or 57 percent, were men. As shown in Figure A, these male top wealth holders could be divided roughly into thirds by age, with one-third under 50, one-third 50 but not yet 65 , and the other third 65 and older.

Female top wealth holders, who accounted for 43 percent of the total, had a significantly different age distribution. While the percentage of female top wealth holders ages 50 under 75 was nearly identical to that of their male counterparts, only about 26 percent were under 50 . In contrast, individuals 75 and older made up a larger percentage of female top wealth holders than male top wealth holders.

[^0]As shown in Figure B, the marital status of top wealth holders also varied considerably by sex. While a large majority of wealthy males, 70.5 percent, was married, only about half of their female counterparts had this marital status. Similarly, a higher percentage of wealthy males was single compared to female top wealth holders. In contrast, nearly one-quarter of women were widowed compared to only 6.8 percent of men.

## Figure A

| Other [2] | 220 | 14.1 | 129 | 11.0 |

[1] Top wealth holders are defined as individuals with gross assets of at least \$1.5 million.
[2] Includes individuals who were separated or divorced or those for whom marital status could not be determined.
NOTE: Detail may not add to totals because of rounding.

## Asset Portfolios

As shown in Figure C, the portfolio composition for male top wealth holders varied considerably by size of net worth. Real estate, including personal resi-
dences, was the most dominant portfolio component for those with net worth under $\$ 1.5$ million, but made up a significantly smaller portion of the portfolio of their wealthier counterparts.

While male top wealth holders with net worth of less than $\$ 1.5$ million held 40.6 percent of their portfolio in real estate, including the personal residence, for men with net worth of $\$ 10$ million or more, this portion was only 12.6 percent. The pattern was similar for retirement assets, including Individual Retirement Accounts (IRAs), annuities, and self-employed or Keogh plans, which accounted for over 15.0 percent of the portfolio of male top wealth holders with net worth under $\$ 10$ million but only 4.0 percent for men with net worth of $\$ 10$ million or more.

In contrast, equities, including closely held and publicly traded stock, made up a larger portion of the portfolios of wealthier men relative to their younger counterparts. While these assets accounted for 14.9 percent of the portfolio of top wealth holders with net worth under $\$ 1.5$ million, they made up more than twice this percentage, 40.9 percent, in the portfolio of individuals with net worth of $\$ 10$ million or more. This result is consistent with academic research demonstrating that wealthier investors allocate a greater share of their financial assets to equity investments. ${ }^{4}$

Figure D shows that the portfolio holdings for female top wealth holders were similar to those of males, although several differences are notable. In each wealth category, female top wealth holders held proportionately more of their assets in personal residences and publicly traded stock than their male counterparts, and less in closely held stock and business assets, including noncorporate businesses, farms, and limited partnerships.

For individuals with net worth of $\$ 10$ million or more, men and women held a nearly identical percentage of their portfolios in equities, about 40 percent, although the allocation between publicly traded stock and closely held stock was quite different for men than for women. While men in this top wealth category split their equity holdings nearly evenly, 52 percent in publicly traded stock and 48 percent in closely held stock, their female counterparts held 77 percent of their stock holdings in publicly traded companies compared to only 23 percent in closely held companies.

[^1]
[1] Top wealth holders are defined as individuals with gross assets of at least $\$ 1.5$ million.
[2] Includes cash and cash management accounts.
[3] Includes all government bonds, bonds issued by corporations and foreign governments, mortgages and notes, cash value life insurance, and diversified mutual funds 4] Includes Individual Retirement Accounts, annuities, and self-employed or Keogh plans.
[5] Includes noncorporate businesses, farms, and limited partnerships.

Some of the differences between the asset portfolios of male and female top wealth holders can be attributed to the differing age distributions of the two groups. For example, as mentioned above, male top wealth holders in each net worth category held a higher percentage of their portfolios in closely held stock relative to females. Some of this disparity, however, is due to the fact that the age distribution of female top wealth holders is skewed more toward the older age categories than is true for males, as shown in Figure A. As shown in Figures E and F, top wealth holders 65 and older held a markedly lower percentage of their portfolios in closely held stock than their
younger counterparts, although, in each age category, men held proportionately more than women.

In general, the differences in portfolio composition between age groups are not as large as the differences between wealth groups shown above. Even so, several patterns based on age can be observed. For both male and female top wealth holders, personal residences and closely held stock accounted for a smaller percentage of the portfolio held by older individuals than that of their younger counterparts.

In contrast, for both genders, the percentage of the portfolio held in publicly traded stock was lowest for individuals 50 under 65 but highest for those

## Figure D

Female Top Wealth Holders: Selected Assets as a Percentage of Total Assets, by Size of Net Worth, 2004 [1]

[^2]65 and older, although, in each age category, women held more proportionately more than men. Taken as a whole, Figures C through F show that the portfolio allocation of top wealth holders in 2004 reflected preferences based on, age, gender, and wealth level.

## Debts and Mortgages

Figure G shows the debts and mortgages of top wealth holders in 2004 as a percentage of total assets, by sex and age. Two main trends can be observed. First, the debt-to-assets ratio for both men and women was significant lower for older top
wealth holders than for their younger counterparts. This is consistent with the economic theory which predicts that individuals will take on greater debt early in their working lives in order to finance a desired lifestyle. ${ }^{5}$

Although data are not available separately on holdings of mortgage debt, much of the difference in overall debt-to-assets ratios between age groups is likely related to mortgage debt held on primary residences. Data collected as part of the Federal Reserve Board's Survey of Consumer Finances demonstrate that families headed by younger individuals are much

[^3]
## Figure E

Male Top Wealth Holders: Selected Assets as a Percentage of Total Assets, by Age, 2004 [1] Percentage

[1] Top wealth holders are defined as individuals with gross assets of at least $\$ 1.5$ million. [2] Includes cash and cash management accounts.
[3] Includes all government bonds, bonds issued by corporations and foreign governments, mortgages and notes, cash value life insurance, and diversified mutual funds.
[4] Includes Individual Retirement Accounts, annuities, and self-employed or Keogh plans.
[5] Includes noncorporate businesses, farms, and limited partnerships.
more likely to hold mortgage debt on residential property, and have considerably higher average mortgage balances when present, than families headed by older individuals. ${ }^{6}$

The second main trend that can be observed in Figure G is that female top wealth holders in each category had a significantly lower debt-to-assets ratio than their male counterparts. The relative difference in the ratios between genders was largest for top wealth holders under age 50, where the debt-to-assets ratio for men was 17.7 percent, compared to 10.1 percent for women.

## Net Worth

Net worth, defined as total assets minus mortgages and other debts, is a subject of interest among researchers and the general public because, relative to total assets, it represents a more complete picture of an individual's financial position. The 2.7 million top wealth holders in 2004 held a combined $\$ 10.2$ trillion in net worth, for an average of over $\$ 3.7$ million.

Figure H, however, reveals that the average net worth of these individuals varied considerably by age and sex. For both male and female top wealth holders, average net worth for older individuals was high-

## Figure $F$

Female Top Wealth Holders: Selected Assets as a Percentage of Total Assets, by Age, 2004 [1]

[1] Top wealth holders are defined as individuals with gross assets of at least $\$ 1.5$ million.
[2] Includes cash and cash management accounts
[3] Includes all government bonds, bonds issued by corporations and foreign governments, mortgages and notes, cash value life insurance, and diversified mutual funds
[4] Includes Individual Retirement Accounts, annuities, and self-employed or Keogh plans.
[5] Includes noncorporate businesses, farms, and limited partnerships.
er than it was for younger individuals. Additionally, the youngest male top wealth holders, those under 50 , had a lower average net worth than their female counterparts, but, in each of the other age groups, men had a higher average net worth than women.

Male top wealth holders under 50 had the lowest average net worth, $\$ 2.5$ million, trailing females in this age group, who had an average net worth of $\$ 3.1$ million. Male top wealth holders 75 under 85 had an average net worth of $\$ 5.3$ million, more than twice that of their under-50 counterparts and virtually identical to the $\$ 5.2$ million average for men 85 and older. Women 75 under 85 had an average net worth
of $\$ 4.3$ million, just below the average for women 85 and older, $\$ 4.4$ million.

As shown in Figure H, a large part of the difference between the average net worth of male and female top wealth holders under 50 is attributable to the fact that men held more debt, as seen by the gap between total assets and net worth. For top wealth holders 65 and older, who held less debt than their younger counterparts, the gap between total assets and net worth is substantially smaller.

For highly skewed distributions, the median is often a better summary measure than the average since the median is less affected by outliers in a

Figure $G$
Top Wealth Holders: Debt and Mortgages as a Percentage of Total Assets, by Sex and Age, 2004 [1] Percentage

[1] Top wealth holders are defined as individuals with gross assets of at least $\$ 1.5$ million
population. As shown in Figure H, the median net worth of top wealth holders showed considerably less variation by age and sex than the average, and the differences in net worth between men and women were smaller.

The median net worth for wealthy males ranged from $\$ 1.6$ million for those under 50 to $\$ 2.4$ million for those 75 under 85. For wealthy females, the median showed even less variation by age, with the smallest median, $\$ 2.0$ million for those under 50, only 19 percent lower than the largest median, \$2.3 million for those 85 and older.

Taken together, the average and median net worth and total asset distributions by age and sex show that the averages are significantly impacted by relatively few extremely wealthy individuals, particularly for male top wealth holders. This relationship can also be seen in the percentile distribution of wealth for top wealth holders by sex, shown in Figure I.

For values below the 25th percentile, female net worth values dominate those for males, while, at the $90^{\text {th }}$ percentile and above, male net worth values dominate. The net worth distribution for men and women between the 25th and 90th percentiles was very similar. While not included in Figure I, the left tail of the net worth distribution for males dips much lower (larger negative values) for points below the 1 st percentile than for females.

## State Data

Figure J shows the States with the largest number of individuals with net worth of $\$ 1.5$ million or more. ${ }^{7}$ California, the nation's most populous State in 2004, also had the largest number of residents with net worth of at least $\$ 1.5$ million, $428,000 .^{8}$ In fact, the State was home to 19.5 percent of all such residents, despite accounting for only 11.9 percent of the U.S. adult population. Florida, with 6.1 percent of the

U.S. adult population, had the second-largest number of residents with net worth of at least $\$ 1.5$ million, 199,000, which accounted for 9.1 percent of the total. New York had the third largest number of residents with net worth of at least $\$ 1.5$ million, 168,000 , or 7.7 percent of the total, but was home to only 6.6 percent of the total U.S. adult population.

The fact that a disproportionate share of the very wealthy lived in California, Florida, and New York is reflected in Figure K, which shows that each of these three States ranked in the top ten in concentration of residents with net worth of at least \$1.5 million. Ranking by concentration eliminates distortions caused by the widely varied populations of the States. Using this measure, Connecticut ranked first with the highest per capita number of residents with net worth of at least $\$ 1.5$ million, 1.8 percent. Two of the smallest States in terms of population, Wyoming and Delaware, as well as the District of Columbia, were also in the top ten. In addition to California, Florida, and New York, two other States-Massachusetts and New Jersey-ranked in

## Figure K

States with the Highest Concentration of Residents with Net Worth of \$1.5 Million or More, 2004
[Numbers are in thousands]

the top ten in both the number of residents with net worth of at least $\$ 1.5$ million and the per capita number of these residents.

The concentration of residents with at least \$1.5 million in net worth, by State, is shown geographically in Figure L. This figure separates the States (including the District of Columbia) into three groups by per capita number of residents with net worth of at least $\$ 1.5$ million. It is interesting to note that the States in the top third, those with the highest number of wealth holders per capita, were geographically distributed fairly evenly across the four major regions of the United States - Northeast, South, Midwest, and West-with four top-third States in each region. ${ }^{9}$

## Top Wealth Holders, 1998-2004

Changes in the top wealth holder population over time are best understood against the backdrop of changes in the U.S. economy, since the financial well-being of top wealth holders is likely to be sig-

## Figure L

Concentration of Top Wealth Holders with Net Worth of \$1.5 Million or More, by State, 2004

[^5]
## Personal Wealth, 2004

Statistics of Income Bulletin | Fall 2008
nificantly affected by the health of the economy as a whole. Over the 2 years between 1998 and 2000, the country experienced a period of rapid economic growth, with real Gross Domestic Product (GDP) increasing a total of 8.3 percent. ${ }^{10}$ Equity prices during this time also increased rapidly. On January 2, 1998, the S\&P 500 stock index closed at 975.04 , but, by March 24, 2000, the index closed at a then-record 1527.46, a 56.7-percent increase in less than 27 months. ${ }^{11}$ Stocks in the technology-laden NASDAQ Composite Index, meanwhile, appreciated even more rapidly during this period, with the index increasing 219.2 percent between January 2, 1998, and its peak close on March 10, 2000. ${ }^{12}$

The period of rapid growth in the economy and stock prices between 1998 and early 2000 gave way to a pronounced retrenchment by the summer of 2001. Between 2000 and 2001, real GDP increased only 0.75 percent. From their March 2000 peaks, the S\&P 500 dropped 28.5 percent by September 10, 2001, while the Nasdaq Composite Index shed nearly two-thirds of its value. Despite the historic nature of the September 11 terrorist attacks, however, both the S\&P 500 and the Nasdaq Composite Index both closed higher on December 31, 2001, than they had on September 10. The National Bureau of Economic Research (NBER) later declared that the economy was in a recession over the period March 2001 through November 2001. ${ }^{13}$

Between 2001 and 2004, the economy recovered gradually, with real GDP increasing a total of 7.9 percent over the 3 year period. Equity prices during this period posted small nominal gains, with the S\&P 500 stock index increasing 5.6 percent from the start of 2002 to the end of 2004, and the Nasdaq Composite Index increasing 11.5 percent.

In the preceding paragraphs, stock index levels are expressed in nominal terms without considering the effects of inflation, which erodes the value of money over time. A look at the real (inflation-adjusted) changes in the value of the stock market between

1998 and 2004 paints a somewhat different picture. The yearly average close for the S\&P 500 index, in constant 2004 dollars, was 2.7 percent higher for 2001 than for 1998, but 10.5 percent lower for 2004 than for 2001. ${ }^{14}$ For the Nasdaq Composite Index, the yearly average close, in constant 2004 dollars, increased 4.2 percent between 1998 and 2001 before falling 7.0 percent between 2001 and $2004 .{ }^{15}$

Although the growth rates of GDP and equity prices experienced considerable turbulence between 1998 and 2004, the value of residential real estate increased steadily throughout this period. Data from the Office of Federal Housing Enterprise Oversight (OFHEO) Home Price Index show a consistent monthly increase from January 1998 through December 2004, with an overall increase of 62.0 percent over this period. ${ }^{16}$ Data from the S\&P/Case-Shiller 10-City Composite Index, which tracks changes in the value of the residential real estate market in 10 major metropolitan regions across the United States, show a similar, steady monthly increase during this period, with an overall increase of 131.5 percent. ${ }^{17}$

As shown in Figure M, the number of individuals with net worth of $\$ 1.5$ million or more, in constant 2004 dollars, increased from just over 1.8 million in 1998 to nearly 2.2 million in 2004. Nearly all of this 21.5-percent increase occurred between 1998 and 2001, as the number stayed nearly constant between 2001 and 2004. This is likely due, in part, to the relatively stronger performance of the equity markets in the earlier 3 -year period. As will be shown below, stock was a dominant portfolio component of top wealth holders throughout this period. Therefore, the relatively stronger performance of the stock market between 1998 and 2001 than in the later three-year period is likely to have impacted the number of individuals with net worth of $\$ 1.5$ million or more.

Figure M also shows that the growth in the number of individuals with net worth of $\$ 1.5$ million or more between 1998 and 2004 varied by net worth category. The growth in the number of these top

[^6]
## Figure M

| Number of Top Wealth Holders with Net Worth of $\$ 1.5$ Million or More, by Size of Net Worth, 1998-2004 <br> [Numbers are in thousands] |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
| Size of net worth, in constant 2004 dollars [1] 2004 dollars [1] | 1998 | 2001 | 2004 | Percentage growth, 1998-2004 |
|  | (1) | (2) | (3) | (4) |
| Total | 1,807 | 2,193 | 2,196 | 21.5 |
| \$1.5 million under \$2.0 million | 651 | 754 | 745 | 14.4 |
| \$2.0 million under $\$ 3.5$ million | 685 | 789 | 845 | 23.4 |
| \$3.5 million under $\$ 5.0$ million | 188 | 259 | 248 | 31.9 |
| $\$ 5.0$ million under $\$ 10.0$ million | 189 | 260 | 232 | 22.8 |
| \$10.0 million or more | 94 | 140 | 125 | 33.0 |

[1] Net worth was converted to constant 2004 dollars using the Gross Domestic Product Chain-type Price Index produced by the Bureau of Economic Analysis. See http://research.stlouisfed.org/fred2/series/GDPCTPI.
wealth holders between 1998 and 2001 was most pronounced for those with net worth of $\$ 3.5$ million or more, with more modest gains in the number of individuals with net worth between $\$ 1.5$ million and $\$ 3.5$ million. In contrast, between 2001 and 2004, the number of individuals with net worth of $\$ 3.5$ million or more declined, while the number of those with net worth between $\$ 1.5$ million and $\$ 3.5$ mil-
lion increased. This pattern may reflect, in part, the movement of some top wealth holders from the higher net worth categories into lower net worth categories as their portfolio values declined in real terms.

Changes in the asset portfolio of top wealth holders between 1998 and 2004 are shown in Figure N. For individuals with net worth of $\$ 1.5$ million or more, in constant 2004 dollars, the amount held in stock was nearly $\$ 3.4$ trillion in 1998, $\$ 4.1$ trillion in 2001, but only $\$ 3.3$ trillion in 2004. In contrast, the value of real estate assets held by individuals with this level of wealth increased from almost $\$ 1.4$ trillion in 1998 to $\$ 1.9$ trillion in 2001 and $\$ 2.3$ trillion in 2004.

It is important to note that asset portfolio changes can be arise both from the appreciation or depreciation of asset types, as well as the reallocation of assets within the portfolio. Research suggests that individuals "chase returns" by reallocating their portfolios to shift more resources into assets that have performed well in the recent past, or, conversely, shifting assets away from assets that have performed poorly. ${ }^{18}$ Shifts in the portfolio composition of top wealth holders between 1998 and 2004 suggest that some "return chasing" may have taken place, although these changes may not be statistically significant.

## Figure 0

Percentage of Top Wealth Holders with \$1.5 Million or More in Net Worth, by Age, 1998-2004 [1] Percentage

[1] In constant 2004 dollars using the Gross Domestic Product Chain-type Price Index produced by the Bureau of Economic Analysis. See http://research.stlouisfed.org/ fred2/series/GDPCTPI.

In 1998, over 91 percent of top wealth holders held stock in their portfolios. In 2001, after the significant decline in the stock market beginning in March 2000, a slightly smaller portion of the top wealth holder population, 89 percent, held stock. In 2004, after 3 more years of relatively weak performance in the stock market, less than 87 percent of top wealth holders held stock in their portfolios.

Another way to look at changes in the top wealth holder population between 1998 and 2004 is to look at changes in the age distribution. Figure O shows the percentage of individuals with net worth of $\$ 1.5$ million or more in each of three age groups - under 50 , 50 under 65 , and 65 or older. Overall, the figure shows that the age distribution of these wealthy individuals was relatively stable over time, with the exception being an increase in those under 50 for $2001 .{ }^{19}$

## Concentration Estimates

The share of total U.S. wealth held by the Nation's top wealth holders has long been a topic of interest for researchers and the general public. One way of looking at year-to-year changes in the distribution of wealth is to examine the share of total U.S. wealth held by a constant percentage of the population. Figure $P$ shows the percentages of total U.S. wealth held by the top 1.0 percent and the top 0.5 percent of the population between 1989 and 2004. ${ }^{20}$

In 2004, 1.0 percent of the U.S. adult population was approximately 2.2 million individuals. These individuals owned approximately 19.4 percent of total U.S. individual wealth, a 2.9-percent decrease since 2001, although this difference may not be statistically significant. A similar pattern was evident in the share of wealth held by the over 1.1 million individu-

[^9]
## Figure P

Percentage of Total U.S. Net Worth Held by Top 1 Percent and 0.5 Percent of the U.S. Population, 1989-2004 Percentage

als who made up the top 0.5 percent of the U.S. adult population in 2004. They held about 15.3 percent of the Nation's net worth in 2004, down from 17.9 percent in 2001, although, as noted above, this difference may be within the sampling error of these estimates. Overall, these results suggest that the share of wealth held by the very wealthiest Americans has stayed within a relatively narrow range over the 15year period. ${ }^{21}$

## Summary

An estimated 2.7 million U.S. adults in 2004 had gross assets of $\$ 1.5$ million or more. These top wealth holders combined to hold over $\$ 10.2$ trillion in net worth. A little less than 1.6 million, or 57.0 percent, of top wealth holders were men, while just under 1.2 million were women. Most wealthy individuals of both genders were married, although a significantly higher proportion of wealthy females were widowed compared to widowed wealthy males. Although the median net worth of male and female top wealth holders was similar, men had a significantly higher average net worth, reflecting the
impact of a relatively small number of extremely wealthy men.

The asset portfolio of top wealth holders varied considerably by gender, age, and relative wealth. Women's portfolios contained a greater proportion held in personal residences and publicly traded stock than those of men. Conversely, men's portfolios were made up of proportionately more closely held stock and business assets. For top wealth holders of both genders, the wealthiest individuals held proportionately more of their assets in stock and less in real estate than their less wealthy counterparts. Additionally, the value of the personal residence made up a smaller percentage of the portfolios held by older top wealth holders than in the portfolios held by younger individuals. Men in each age and wealth class had a higher ratio of debts to assets than their female counterparts.

In 2004, California had the largest number of individuals with net worth of $\$ 1.5$ million or more, while Connecticut had the highest per capita population of these very wealthy residents. States with a relatively high concentration of residents with net worth

[^10]
## Personal Wealth, 2004

Statistics of Income Bulletin | Fall 2008
of $\$ 1.5$ million or more were distributed relatively evenly across the major regions of the United States.

Between 1998 and 2004, there was a significant increase in the number of individuals with net worth of $\$ 1.5$ million or more. Most of this increase occurred between 1998 and 2001, as the number of individuals with net worth of $\$ 1.5$ million was nearly identical in 2001 and 2004. The value of stock held by very wealthy individuals increased substantially between 1998 and 2001, before falling in the 2001 through 2004 period. In contrast, the value of real estate held by individuals with net worth of $\$ 1.5$ million or more increased steadily between 1998 and 2004.

## Data Sources and Limitations

Statistics of Income collects data from an annual sample of Federal estate tax returns that are used primarily for policy and budget purposes. The sample follows a 3 -year cycle that is designed mainly to accommodate year-of-death estimates, with each study concentrating on decedents who died in the first year (the focus year) of the 3 -year cycle. The annual samples are also adequate for producing filing-year estimates.

Year-of-death estimates are desirable, because filing extensions and other filing delays mean that returns filed in any given calendar year may represent decedents who died in many different years. Thus, estate tax return data for a single filing year may reflect different economic and tax law conditions. By concentrating on a single year of death, these limitations can be overcome, making it possible to study the data in the context of a single time period.

Returns are selected using a stratified random sample with three stratifying variables. The stratifying variables are: year of death (focus year versus nonfocus years), total gross estate plus certain adjusted taxable gifts made during a decedent's lifetime, and age at death. The gross estate plus gifts variable is divided into four categories: $\$ 1.5$ million under \$2.5 million, \$2.5 million under \$5 million, \$5 million under $\$ 10$ million, and $\$ 10$ million or more. Age at death is also divided into five categories: under 40 , 40 under 50 , 50 under 65 , 65 under 75 , and

75 and older. Sample rates vary from 3 percent to 100 percent, with over half the strata selected with certainty, i.e., at the 100-percent rate.

SOI has combined Federal estate tax returns filed in 2004, 2005, and 2006 to produce the estimates of wealth for 2004 presented here. One of the strengths of estimates derived from SOI samples of estate tax returns is the large sample on which the estimates are based. The 2004 sample includes more than 25,800 returns. ${ }^{22}$

While the sample size and richness of available data make the estimation techniques used in this study attractive, there are limitations to be noted. First, and most important, estate tax returns provide a presumably random sample, stratified by age, not of the total population, but of living persons with gross estates at or above the estate tax filing threshold. Sample rates are approximated by appropriate mortality rates. However, determining appropriate mortality rates for use in calculating sample weights is by no means a straightforward exercise. The Appendix to this article discusses the estate multiplier technique and recent innovations in calculating sample weights for SOI's personal wealth estimates.

Second, while estate tax returns are generally prepared by professionals and are, therefore, likely to be more accurate in detail than survey responses, the values reported are used to compute tax liability, so that there is a natural tendency for the values to be somewhat conservative. This is especially true for hard-to-value assets, such as businesses and certain types of real estate.

It should also be noted that the estate tax data used for these estimates are preaudit figures. A Statistics of Income (SOI) study, based on the results of IRS audits of estate tax returns, estimated that detected undervaluation of assets was about 1.2 percent of total asset holdings. ${ }^{23}$ In addition, it is common to claim substantial discounts when valuing ownership interests of less than 50 percent in small companies, partnerships, and other nonliquid assets. Increasingly, estate planning techniques are used to fracture ownership interests in a variety of business and financial assets to take advantage of these discounts.

[^11]Third, while estate tax returns report assets that are owned outright, total wealth might ideally include wealth to which a person has an income interest but not necessarily actual title. Examples of the latter include defined-benefit pension plans and Social Security benefits.

Finally, the wealth of some individuals near death may differ somewhat from that of the general population in the same age cohort. For some, portfolios may have been altered or simplified to ensure the uninterrupted continuation of an ongoing business or to simplify the task of executing the estate. For others, wealth will have been reduced through expenses related to a final illness. In many cases, effective estate planning may also have reduced the value of the estate reportable for tax purposes.

## Appendix: The Estate Multiplier Technique

The estate multiplier technique assumes that estate tax returns, taken as a whole, represent a random sample of the living wealthy population and thus provide a means of producing reasonable estimates of personal wealth. ${ }^{24}$ Estimates of the wealth holdings of the living population are derived by applying a multiplier, based on appropriate mortality rates, to this sample. The multiplier is equivalent to a sampling weight where the probabilities of selection include the probability of being a decedent and also that of being included in the Statistics of Income sample of estate tax returns.
Mathematically, this is represented as
MULT= $1 /(\mathrm{p} \cdot \mathrm{r})$ where:
$p=$ probability of selection to the estate tax sample, $r=$ mortality rate appropriate to wealthy individuals.

Some smoothing of the multipliers was employed to constrain both tails of the net worth distribution.

The more difficult computation is determining the probability of being a decedent. Mortality rates for
the general population, by age and sex, are available from the National Center for Health Statistics. However, there is much evidence that the wealthy have mortality rates significantly lower than those of the entire population. Research has demonstrated that individuals who are economically or socially better off also live longer, on average, and are healthier. ${ }^{25}$

Factors such as access to better health services, better diet and nutrition, and fewer work-related risks seem to contribute to this phenomenon. If mortality and wealth are inversely related, then mortality rates for the general population, unadjusted for wealth level, will result in multipliers that are too low and, thus, undervalue wealth. Therefore, it is important to determine a mortality rate appropriate to the wealthy decedents in the estate tax return filing population.

There have been a considerable number of attempts to quantify differences between the mortality of the general population and that of the very wealthy, looking at such factors as education, income, and occupation. In years prior to 2001, SOI calculated mortality rates for its Personal Wealth estimates by adjusting mortality rates for the entire population using mortality differentials derived from the National Longitudinal Mortality Study (NLMS) sponsored by the National Institutes of Health.

Starting with the 2001 estimates, however, estate multipliers have been calculated using mortality rates for holders of large dollar value annuity policies obtained from the Society of Actuaries (SOA). This data source has several advantages relative to using the NLMS mortality differentials. First, the annuitant mortality rates are available for every year, in contrast to the NLMS differentials, which are updated on a biennial cycle. Second, use of this source is consistent with other academic research within and outside the IRS. ${ }^{26}$ For consistency, estimates for 1998 used in this article were recalculated using the annuitant mortality rates.

| Other areas [3] | 5 | 28,042 | 5 | 20,270 | 5 | 8,227 | 5 | 1,294 |

[1] While the size of the underlying sample of estate tax returns makes estimates of wealth derived using the estate multiplier technique fairly robust, estimates of wealth by State can be subject to significant year-to-year fluctuations. This is especially true for individuals at the extreme tail of the net worth distribution and for States with relatively small decedent populations.
[2] Includes all stocks, bonds, mutual funds, cash, and cash management accounts.
[3] Includes U.S. territories and possessions.
NOTE: Detail may not add to total due to rounding.

[^0]:    ${ }^{1}$ Estimate of the adult population of the United States in 2004 was obtained from U.S. Bureau of the Census at http://www.censusgov/popest/states/asrh/SC-est2004-01.html. ${ }^{2}$ Estimate of the total net worth of the United States was obtained from household estimates derived from the Board of Governors of the Federal Reserve System's Survey of Consumer Finances (SCF), found in Kennickell, Arthur B. (2006), "Currents and Undercurrents: Changes in the Distribution of Wealth, 1989-2004," http://www.federalreserve.gov/pubs/feds/2006/200613/200613pap.pdf.
    ${ }^{3}$ Estimates of the equity value of life insurance included in total assets were approximated, based on the face value reported on Federal estate tax returns and on the decedent's age. A ratio of the equity value to the face value was developed, using data from wealthy respondents to the 2004 Board of Governors of the Federal Reserve System's Surveys of Consumer Finances (SCF). A simple regression was used to predict the values used in the Statistics of Income estimates.

[^1]:    ${ }^{4}$ See, for example, Ackert, Lucy F. et al. (2002), "The Asset Allocation Decision and Investor Heterogeneity: A Puzzle?" Journal of Economic Behavior and Organization, Volume 47, pp. 423-433.

[^2]:    [1] Top wealth holders are defined as individuals with gross assets of at least $\$ 1.5$ million.
    [2] Includes cash and cash management accounts
    [3] Includes all government bonds, bonds issued by corporations and foreign governments, mortgages and notes, cash value life insurance, and diversified mutual funds.
    [4] Includes Individual Retirement Accounts, annuities, and self-employed or Keogh plans.
    [5] Includes noncorporate businesses, farms, and limited partnerships.

[^3]:    ${ }^{5}$ See, for example, Modigliani, Franco (1986), "Life Cycle, Individual Thrift, and the Wealth of Nations," American Economic Review, Volume 68, pp. 547-560.

[^4]:    7 While the size of the underlying sample of estate tax returns makes estimates of wealth derived using the estate multiplier technique fairly robust, estimates of wealth by State can be subject to significant year-to-year fluctuations. This is especially true for individuals at the extreme tail of the net worth distribution and for States with

[^9]:    19 At least a portion of this increase can be attributed to sampling variance; in particular, on the unusually large number of relatively young, wealthy individuals who died as a result of the terrorist attacks of September 11, 2001. The estate multipliers, or sample weights, used to produce these wealth estimates are computed using mortality rates that are smoothed to minimize normal year-to-year variations in the U.S. decedent population. These rates cannot easily be adjusted to accurately reflect the mortality rate actually experienced by this subpopulation due to these tragic events, meaning that the resulting estimates of wealth for young, wealthy individuals in the living population based on data reported for these decedents may be biased slightly upward.
    20 U.S. Census Bureau, 2004.

[^10]:    ${ }^{21}$ These results are similar to with those derived from the Federal Reserve Board’s Survey of Consumer Finances (Kennickell, 2006).

[^11]:    22 Although the overall sample of estate tax returns is large, the number of decedents who were young (less than 40) or extremely wealthy (gross assets of $\$ 5$ million or more) in any given year varies considerably and is small in comparison to their numbers in the living population. Because of this, the resulting estimates of wealth for these two categories of living individuals would be subject to significant fluctuations from period to period. To reduce this variance, the sample is "smoothed" by including all returns for young or wealthy decedents filed during the 3-year sample period without regard to their years of death. These segments of the sample are then poststratified and reweighted to represent the true decedent population for the year of interest. This technique reduces the effect of outliers on estimates of personal wealth.
